Debug a problem with a Cloud Deployment and Fix it

ngooglecoursera.qwiklabs.com/focuses/47757

Introduction

You're an IT administrator in a small-sized startup that runs a web server named ws01 in the cloud. One day, when you try to access the website served by ws01, you get an HTTP Error 500. Since your deployment is still in an early stage, you suspect a developer might have used this server to do some testing or run some experiments. Now you need to troubleshoot ws01, find out what's going on, and get the service back to a healthy state.

Error detection

Open the website served by wso1 by typing the external IP address of ws01 in a web browser. The external IP address of ws01 can be found in the Connection Details Panel on the left-hand side.

You should now find **500 Internal Server Error!** on the webpage. Later, during this lab, you'll troubleshoot this issue.

What you'll do

- Understand what http status code means
- Learn how to check port status with the netstat command
- Learn how to manage services with the systemctl command
- Know how to monitor system resources and identify the root cause of an issue

You'll have 90 minutes to complete this lab.

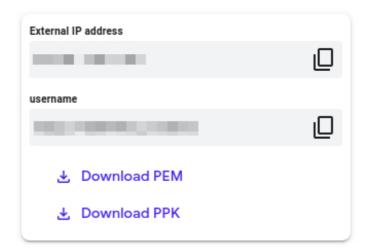

Start the lab

You'll need to start the lab before you can access the materials in the virtual machine OS. To do this, click the green "Start Lab" button at the top of the screen.

Note: For this lab you are going to access the **Linux VM** through your **local SSH Client**, and not use the **Google Console** (**Open GCP Console** button is not available for this lab).

After you click the "Start Lab" button, you will see all the SSH connection details on the left-hand side of your screen. You should have a screen that looks like this:

Accessing the virtual machine

Please find one of the three relevant options below based on your device's operating system.

Note: Working with Qwiklabs may be similar to the work you'd perform as an **IT Support Specialist**; you'll be interfacing with a cutting-edge technology that requires multiple steps to access, and perhaps healthy doses of patience and persistence(!). You'll also be using **SSH** to enter the labs -- a critical skill in IT Support that you'll be able to practice through the labs.

Option 1: Windows Users: Connecting to your VM

In this section, you will use the PuTTY Secure Shell (SSH) client and your VM's External IP address to connect.

Download your PPK key file

You can download the VM's private key file in the PuTTY-compatible **PPK** format from the Qwiklabs Start Lab page. Click on **Download PPK**.

Connect to your VM using SSH and PuTTY

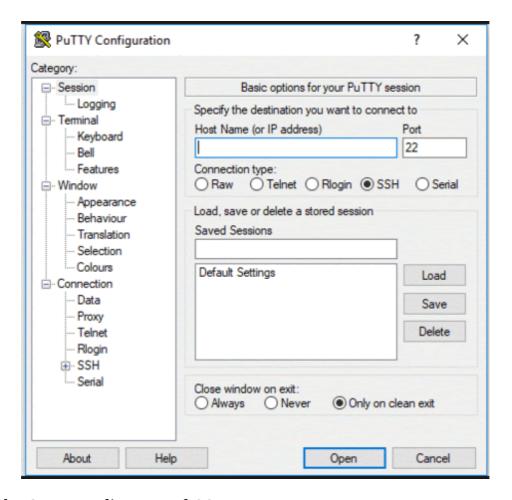

1. You can download Putty from here

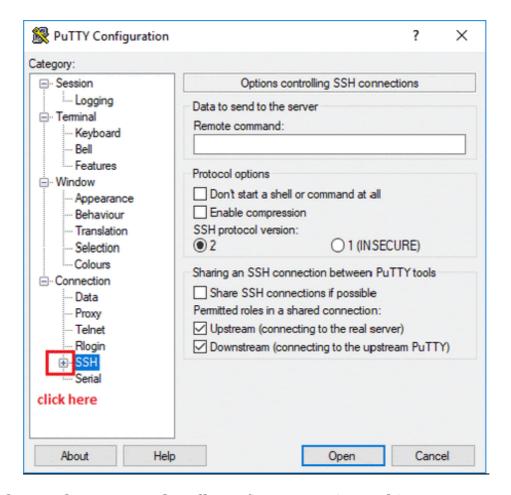

2. In the **Host Name (or IP** address) box, enter username@external_ip_address.

Note: Replace **username** and **external_ip_address** with values provided in the lab.

- 3. In the **Category** list, expand **SSH**.
- 4. Click Auth (don't expand it).
- 5. In the **Private key file for authentication** box, browse to the PPK file that you downloaded and double-click it.
- 6. Click on the **Open** button.

Note: PPK file is to be imported into PuTTY tool using the Browse option available in it. It should not be opened directly but only to be used in PuTTY.

7. Click **Yes** when prompted to allow a first connection to this remote SSH server. Because you are using a key pair for authentication, you will not be prompted for a password.

Common issues

If PuTTY fails to connect to your Linux VM, verify that:

- You entered **<username>**@**<external ip address>** in PuTTY.
- You downloaded the fresh new PPK file for this lab from Qwiklabs.
- You are using the downloaded PPK file in PuTTY.

Option 2: OSX and Linux users: Connecting to your VM via SSH

Download your VM's private key file.

You can download the private key file in PEM format from the Qwiklabs Start Lab page. Click on **Download PEM**.

Connect to the VM using the local Terminal application

A **terminal** is a program which provides a **text-based interface for typing commands**. Here you will use your terminal as an SSH client to connect with lab provided Linux VM.

- 1. Open the Terminal application.
 - To open the terminal in Linux use the shortcut key **Ctrl+Alt+t**.
 - To open terminal in Mac (OSX) enter cmd + space and search for terminal.
- 2. Enter the following commands.

Note: Substitute the **path/filename for the PEM** file you downloaded, **username** and **External IP Address**.

You will most likely find the PEM file in **Downloads**. If you have not changed the download settings of your system, then the path of the PEM key will be

~/Downloads/qwikLABS-XXXXX.pem

chmod 600 ~/Downloads/qwikLABS-XXXXX.pem

ssh -i ~/Downloads/gwikLABS-XXXXX.pem username@External Ip Address

```
:-$ ssh -i ~/Downloads/qwikLABS-L923-42090.pem gcpstagingeduit1370_student@35.239.106.192
The authenticity of host '35.239.106.192 (35.239.106.192)' can't be established.
ECDSA key fingerprint is SHA256:vrz8b4aYUtruFh0A6wZn6Ozy1oqqPEfh931olvxiTm8.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added '35.239.106.192' (ECDSA) to the list of known hosts.
Linux linux-instance 4.9.0-9-amd64 #1 SMP Debian 4.9.168-1+deb9u2 (2019-05-13) x86_64
The programs included with the Debian GNU/Linux system are free software;
the exact distribution terms for each program are described in the
individual files in /usr/share/doc/*/copyright.

Debian GNU/Linux comes with ABSOLUTELY NO WARRANTY, to the extent
permitted by applicable law.
gcpstagingeduit1370_student@linux-instance:-$
```

Option 3: Chrome OS users: Connecting to your VM via SSH

Note: Make sure you are not in **Incognito/Private mode** while launching the application.

Download your VM's private key file.

You can download the private key file in PEM format from the Qwiklabs Start Lab page. Click on **Download PEM**.

Connect to your VM

1. Add Secure Shell from <u>here</u> to your Chrome browser.

2. Open the Secure Shell app and click on [New Connection].

3. In the **username** section, enter the username given in the Connection Details Panel of the lab. And for the **hostname** section, enter the external IP of your VM instance that is mentioned in the Connection Details Panel of the lab.

4. In the **Identity** section, import the downloaded PEM key by clicking on the **Import...** button beside the field. Choose your PEM key and click on the **OPEN** button.

Note: If the key is still not available after importing it, refresh the application, and select it from the **Identity** drop-down menu.

5. Once your key is uploaded, click on the **[ENTER] Connect** button below.

- 6. For any prompts, type **yes** to continue.
- 7. You have now successfully connected to your Linux VM.

You're now ready to continue with the lab!

Debug the issue

HTTP response status codes indicate whether a specific <u>HTTP</u> request has been successfully completed. Responses are grouped into five classes:

- Informational responses (100–199)
- Successful responses (200–299)
- Redirects (300–399)
- Client errors (400–499)
- Server errors (500–599)

The HyperText Transfer Protocol (HTTP) **500 Internal Server Error** response code indicates that the server encountered an unexpected condition that prevented it from fulfilling the request. Before troubleshooting the error, you'll need to understand more about systemctl.

systemctl is a utility for controlling the systemd system and service manager. It comes with a long list of options for different functionality, including starting, stopping, restarting, or reloading a daemon.

Let's now troubleshoot the issue. Since the webpage returns an HTTP error status code, let's check the status of the web server i.e apache2.

sudo systemctl status apache2

The command outputs the status of the service.

Output:

The outputs say "Failed to start The Apache HTTP Server." This might be the reason for the HTTP error status code displayed on the webpage. Let's try to restart the service using the following command:

```
sudo systemctl restart apache2
```

Output:

```
gcpstaging100395_student@ws01:~$ sudo systemctl restart apache2
Job for apache2.service failed because the control process exited with error code.
See "systemctl status apache2.service" and "journalctl -xe" for details.
```

Hmm this command also fails. Let's check the status of the service again and try to find the root cause of the issue.

```
sudo systemctl status apache2
```

Output:

Take a close look at the output. There's a line stating "Address already in use: AH00072: make_sock: could not bind to address [::]:80." The Apache webserver listens for incoming connection and binds on port 80. But according to the message displayed, port 80 is being used by the other process, so the Apache web server isn't able to bind to port 80.

To find which processes are listening on which ports, we'll be using the netstat command, which returns network-related information. Here, we'll be using a combination of flags along with the netstat command to check which process is using

a particular port:

```
sudo netstat -nlp
```

Output:

```
Proto Recv-Q Send-Q Local Address
tcp 0 0 0.0.0.0:80
                                                                        Foreign Address
                                                                                                                                   PID/Program name
                                                                                                                                   2283/python3

                                                                                                                                   /run/user/1898256998/systemd/private
/run/user/1898256998/gnupg/S.gpg-agent.browser
```

You can see a process ID (PID) and an associated program name that's using port 80. A python3 program is using the port.

Note: Jot down the PID of the python3 program in your local text editor, which will be used later in the lab.

Let's find out which python3 program this is by using the following command:

```
ps -ax | grep python3
```

Output:

There is a list of python3 processes displayed here. Now, look out for the PID of the process we're looking for and match it with the one that's using port 80 (output from netstat command).

You can now obtain the script /usr/local/bin/jimmytest.py by its PID, which is actually using port 80.

Have a look at the code using the following command:

```
cat /usr/local/bin/jimmytest.py
```

This is indeed a test written by developers, and shouldn't be taking the default port.

Let's kill the process created by /usr/local/bin/jimmytest.py by using the following command:

```
sudo kill [process-id]
```

Replace [process-id] with the PID of the python3 program that you jotted down earlier in the lab.

List the processes again to find out if the process we just killed was actually terminated.

```
ps -ax | grep python3
```

This time you'll notice that similar process running again with a new PID.

This kind of behavior should be caused by service. Since this is a python script created by Jimmy, let's check for the availability of any service with the keywords " python " or " jimmy ".

```
sudo systemctl --type=service | grep jimmy
```

Output:

```
gcpstaging100395_student@ws01:~$ sudo systemctl --type=service | grep jimmy

■ jimmytest.service loaded failed failed Jimmy python test service
```

There is a service available named **jimmytest.service**. We should now stop and disable this service using the following command:

sudo systemctl stop jimmytest && sudo systemctl disable jimmytest

Output:

```
gcpstaging100395_student@ws01:~$ sudo systemctl stop jimmytest && sudo systemctl disable jimm
ytest
Removed /etc/systemd/system/default.target.wants/jimmytest.service.
```

The service is now removed.

To confirm that no processes are listening on 80, using the following command:

```
sudo netstat -nlp
```

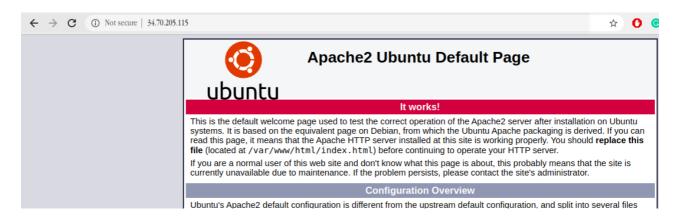

Output:

```
-$ sudo netstat
Active Internet connections (only servers)
Proto Recv-Q Send-Q Local Address
                                              Foreign Address
                                                                                     PID/Program name

           0
                                                                                     1952/chronyd
                    ::1:323
           0
                                                                                     760/systemd-network
```

Since there are no processes listening on port 80, we can now start apache2 again.

sudo systemctl start apache2

You should now be able to see the **Apache2 Ubuntu Default Page**.

Click *Check my progress* to verify the objective. Debug and Fix the server error

Congratulations!

You've successfully fixed the website served by the ws01 and brought the service back to a healthy state! Nice work.

End your lab

When you have completed your lab, click **End Lab**. Qwiklabs removes the resources you've used and cleans the account for you.

You will be given an opportunity to rate the lab experience. Select the applicable number of stars, type a comment, and then click **Submit**.

The number of stars indicates the following:

- 1 star = Very dissatisfied
- 2 stars = Dissatisfied

- 3 stars = Neutral
- 4 stars = Satisfied
- 5 stars = Very satisfied

You can close the dialog box if you don't want to provide feedback.

For feedback, suggestions, or corrections, please use the **Support** tab.
